## 2 Model

### 2.1 Definitions

We consider a directed graph  $G = (V, A)$  modelling a network. Each arc  $(u, v)$  in  $A$  is labeled by an integer  $dl(u, v) \geq 1$  that we call the delay and which represents the number of time slots taken by a signal to go from  $u$  to  $v$  using this arc.

A **route**  $r$  in  $G$  is a sequence of consecutive arcs  $a_0, \dots, a_{k-1}$ , with  $a_i = (u_i, u_{i+1}) \in A$ . We will often refer to the first element of the route as a source and the last as a target.

The **latency** of a vertex  $u_i$  in  $r$ , with  $i \geq 1$ , is defined by

$$\lambda(u_i, r) = \sum_{0 \leq j < i} dl(a_j)$$

We also define  $\lambda(u_0, r) = 0$ . The latency of the route  $r$  is defined by  $\lambda(r) = \lambda(u_k, r)$ .

A **routing function**  $\mathcal{R}$  in  $G$  associates to each pair of vertices  $(u, v)$  a route from  $u$  to  $v$ . Let  $\mathcal{C}$  be an **assignment** in  $G$ , i.e., a set of couples of different vertices of  $G$ . We denote by  $\mathcal{R}_{\mathcal{C}}$  the set of routes  $\mathcal{R}(u, v)$  for any  $(u, v)$  in  $\mathcal{C}$ . We call  $\mathcal{R}_{\mathcal{C}}$  a **routage graph**, it contains all the informations needed in the forthcoming problems (assignment, routes and delays of the arcs).

**TODO:** Si on s'en sert, ajouter ici que le routage est cohérent.

## 2.2 Slotted time Model

Consider now a positive integer  $P$  called the **period**. In our problem, we send in the network messages with period  $P$ . The time will thus be cut into slices of  $P$  discrete slots. Assume we send a message at the source of the route  $r$ , at the time slot  $m$  in the first period, then a message will be sent at time slot  $m$  at each new period. We define the first time slot at which the message reaches a vertex  $v$  in this route by  $t(v, r) = m + \lambda(v, r) \bmod P$ .

A message usually cannot be transported in a single time slot. We denote by  $\tau$  the number of consecutive slots necessary to transmit a message. Let us call  $[t(v, r)]_{P, \tau}$  the set of time slots used by  $r$  at a vertex  $v$  in a period  $P$ , that is  $[t(v, r)]_{P, \tau} = \{t(v, r) + i \bmod P \mid 0 \leq i < \tau\}$ . Usually  $P$  and  $\tau$  will be clear from the context and we will denote  $[t(v, r)]_{P, \tau}$  by  $[t(v, r)]$ .

A  $(P, \tau)$ -**periodic affectation** of a routage graph  $\mathcal{R}_C$  is a sequence  $\mathcal{M} = (m_0, \dots, m_{c-1})$  of  $n$  integers that we call **offsets**, with  $n$  the number of routes in  $\mathcal{R}_C$ . The number  $m_i$  represents the index of the first slot used in a period by the route  $r_i \in \mathcal{R}_C$  at its source. A  $(P, \tau)$ -periodic affectation must have no **collision** between two routes in  $\mathcal{R}_C$ , that is  $\forall (r_i, r_j) \in \mathcal{R}_C^2, i \neq j$ , we have

$$[t(u, r_i)] \cap [t(u, r_j)] = \emptyset.$$

As an example of a  $(2, 1)$ -periodic affectation, let consider a routage graph with routes  $\{r_i\}_{i=1, \dots, n}$ , such that all pairs of routes intersect at a different edge. We set  $\tau = 1$  and the delays are chosen so that if  $r_i$  and  $r_j$  have  $v$  as first common vertex then we have  $\lambda(v, r_i) - \lambda(v, r_j) = 1$ . There is a  $(2, 1)$ -periodic affectation by setting all  $m_i$  to 0.

Figure 1: A routage graph with  $(0, \dots, 0)$  as a  $(2, 1)$ -periodic affectation

## 2.3 Problems

We want to ensure that there is an affectation which allows to send periodic messages from sources to target without collisions. The problem we need to

solve is thus the following:

**Periodic Routes Assignment (PRA)**

**Input:** a routage graph  $\mathcal{R}_C$ , an integer  $\tau$  and an integer  $P$ .

**Question:** does there exist a  $(P, \tau)$ -periodic affectation of  $\mathcal{R}_C$  ?

We will prove in Sec. 3 that the problem PRA is NP-complete, even in restricted settings. Even approximating the smallest value of  $P$  for which there is a  $(P, \tau)$ -periodic affectation is hard.

An unusual property of affectation is that given a routage graph, we may have a  $(P, \tau)$ -periodic affectation but no  $(P', \tau)$ -periodic affectation with  $P' > P$ : the existence of an affectation is not monotone with regards to  $P$ .

**Lemma 1.** *For any odd  $P$ , there is a routage graph such that there is  $(2, 1)$ -periodic affectation but no  $(P, 1)$ -periodic affectation.*

*Proof.* Consider the routage graph  $\mathcal{R}_C$  given in the previous subsection. We change the delays so that for  $v$ , the first vertex which belongs to  $r_i$  and  $r_j$ , we have  $\lambda(v, r_i) - \lambda(v, r_j) = P$ , where  $P$  is an odd number smaller than  $n$ , the number of routes in  $\mathcal{R}_C$ . In such a graph, there is no  $(P, \tau)$ -periodic affectation, because of  $P < n$ .

If we consider a period of 2, for all  $i \neq j$ ,  $\lambda(v, r_i) - \lambda(v, r_j) \bmod 2 = 1$ . Therefore  $(0, \dots, 0)$  is a  $(2, 1)$ -periodic affectation of  $\mathcal{R}_C$ .

□

In the context of cloud-RAN applications, we consider here the digraph  $G = (V, A)$  modeling the target network and two disjoint subsets of vertices  $S$  and  $T$  of equal cardinality, where  $S$  is the set of RRHs and  $T$  is the set of BBUs. A **symmetric** assignment  $\mathcal{C}$ , is an involutive function from  $S$  to  $T$ , which maps each element  $s \in S$  to  $\mathcal{C}(s)$  and  $\mathcal{C}(s)$  to  $s$ . It can also be seen as the set of pairs  $(s, \mathcal{C}(s))$  and  $(\mathcal{C}(s), s)$ .

The Routing function  $\mathcal{R}$  associates to each couple  $(s, \mathcal{C}(s))$  a route called  $r_s$  and to each couples  $(\mathcal{C}(s), s)$  a route called  $r_{\mathcal{C}(s)}$ .

We are given a period  $P$ , a routing function  $\mathcal{R}$ , and we consider a  $(P, \tau)$ -periodic affectation of  $\mathcal{R}_C$  which associates  $m_s$  to the route  $r_s$  which begins by  $s$ , and  $m_{\mathcal{C}(s)}$  to the routes  $r_{\mathcal{C}(s)}$  which begins by  $\mathcal{C}(s)$ . This affectation represents the following process: first a message is sent at  $s$ , through the route  $r_s$ , at time  $m_s$ .

This message is received by  $\mathcal{C}(s)$  at time  $t(\mathcal{C}(s), r_s)$ . It is then sent back to  $s$  in the same period at time  $m_{\mathcal{C}(s)}$  if  $m_{\mathcal{C}(s)} > t(\mathcal{C}(s), r_s)$ , otherwise at time  $m_{\mathcal{C}(s)}$  in the next period. The time between the arrival of the message and the time it is sent back is called the **waiting time** and is defined by  $w_s = m_{\mathcal{C}(s)} - t(\mathcal{C}(s), r_s)$  if  $m_{\mathcal{C}(s)} > t(\mathcal{C}(s), r_s)$  and  $w_s = m_{\mathcal{C}(s)} + P - t(\mathcal{C}(s), r_s)$  otherwise.

When a BBU receives a message, it must compute the answer before sending it back to the RRH. This time can be encoded in the last arc leading to the BBU and thus we need not to consider it explicitly in our model.

Thus, the whole process time for a message sent at vertex  $s$  is equal to

$$PT(s) = \lambda(r_s) + w_s + \lambda(r_{\mathcal{C}(s)}).$$

The **maximum process time** of the  $(P, \tau)$ -periodic affectation  $\mathcal{M}$  is defined by  $MT(\mathcal{M}) = \max_{s \in S} PT(s)$ . The problem we want to solve is the following.

### Periodic Assignment for Low Latency(PALL)

**Input:** A routage graph  $\mathcal{R}_{\mathcal{C}}$  with  $\mathcal{C}$  a symmetric assignment, a period  $P$ , an integer  $\tau$ , an integer  $T_{max}$ .

**Question:** does there exist a  $(P, \tau)$ -periodic affectation  $\mathcal{M}$  of  $\mathcal{R}_{\mathcal{C}}$  such that  $MT(\mathcal{M}) \leq T_{max}$ ?

*TODO: Si on veut, on peut parler du temps moyen aussi ici, seulement si on fait quelque chose dessus dans la suite*

In this article, we works on given routages, but we could imagine a problem, in which, considering a given graph  $G = (V, A)$  and a period  $P$ , the question is to find, if it exists, a routage graph  $\mathcal{R}_{\mathcal{C}}$ , in which there is  $(P, \tau)$ -periodic affectation.

## 3 Solving PRA

### 3.1 NP-Hardness

In this section we assume that the size of a message  $\tau$  is equal to one. We will prove the hardness of PRA and PALL for this parameter, which implies the hardness of the general problems. Consider an instance of the problem PRA, i.e., a routage graph  $\mathcal{R}_{\mathcal{C}}$ , a message size  $\tau$  and a period  $P$ .

The **conflict depth** of a route is the number of other routes which share an edge with it. The conflict depth of a routage graph  $\mathcal{R}_{\mathcal{C}}$  is the maximum of the conflict depth of the routes in  $\mathcal{R}_{\mathcal{C}}$ .

The **load** of a routage graph is the maximal number of routes sharing the same arc. It is clear that a  $(P, \tau)$ -periodic affectation must satisfy that  $P$  is larger or equal to the load times  $\tau$ .

We give two alternate proofs that PRA is NP-complete. The first one works for conflict depth 2 and is minimal in this regards since we later prove that for conflict depth one, it is easy to solve PRA. The second one reduces the problem to graph coloring and implies inapproximability when one tries to minimize the

parameter  $P$ .

**Proposition 1.** *Problem PRA is NP-complete, when the routing is of conflict depth two.*

*Proof.* The problem PRA is in NP since given an offset for each route in an affectation, it is easy to check in linear time in the number of edges whether there are collisions.

Let  $H = (V, E)$  be a graph and let  $d$  be its maximal degree. We consider the problem to determine whether  $H$  is edge-colorable with  $d$  or  $d + 1$  colors. The edge coloring problem is NP-hard [1] and we reduce it to PRA to prove its NP-hardness. We define from  $H$  an instance of PRA as follows. The graph  $G$  has for vertices  $v_1, v_2$  for each  $v$  in  $V$  and  $s_{u,v}, t_{u,v}$  for each  $(u, v) \in E$ . The set  $A$  of arcs of  $G$  is:

$$\{(v_1, v_2) \mid v \in V\} \cup \{(u_2, v_1) \mid u \neq v \in V\} \cup \{(s_{u,v}, u_1), (v_2, t_{u,v}) \mid (u, v) \in E\}.$$

All these arcs are of weight 0. For each edge  $(u, v) \in E$ , there is a route  $s_{u,v}, u_1, u_2, v_1, v_2, t_{u,v}$  in  $\mathcal{R}$ . The affectation  $\mathcal{C}$  is the set of pair of vertices  $(s_{u,v}, t_{u,v})$ .

Observe that the existence of a  $d$ -coloring of  $H$  is equivalent to the existence of a  $(d, 1)$ -periodic affectation of  $\mathcal{R}_{\mathcal{C}}$ . Indeed, a  $d$ -coloring of  $H$  can be seen as a labeling of its edges by the integers in  $\{0, \dots, d - 1\}$  and we have a bijection between  $d$ -colorings of  $H$  and offsets of the routes of  $\mathcal{R}_{\mathcal{C}}$ . By construction, the constraint of having no collision between the routes is equivalent to the fact that no two adjacent edges have the same color. Therefore we have reduced edge coloring to PRA which concludes the proof.  $\square$

**TODO:** Faire un dessin d'illustration ?

Remark that we have used zero weight in the proof. If we ask the weights to be strictly positive, which makes sense in our model since they represent the latency of physical links, it is easy to adapt the proof. We just have to set them so that in any route the delay at  $u_1$  is equal to  $d$  and thus equal to 0 modulo  $d$ . We now lift this hardness result to the problem PALL.

**Corollary 1.** *Problem PALL is NP-complete for routing of conflict depth two.*

*Proof.* We consider  $(\mathcal{R}_{\mathcal{C}}, P, \tau)$  an instance of PRA. We assume that no vertex appears both in the first and second position in a pair of  $\mathcal{C}$ . Remark that this condition is satisfied in the previous proof, which makes the problem PRA restricted to this kind of instances NP-complete. Let us define  $T_{max} = 2 \times \max_{r \in \mathcal{R}} \lambda(r) + P$ . We consider  $\mathcal{C}'$  and  $\mathcal{R}'_{\mathcal{C}'}$  symmetrized versions of  $\mathcal{C}$  and  $\mathcal{R}_{\mathcal{C}}$  where for every route there is a symmetric route with new arcs and the same weights. The instance  $(\mathcal{R}'_{\mathcal{C}'}, P, \tau, T_{max})$  is in PALL if and only if  $(\mathcal{R}_{\mathcal{C}}, P, \tau)$  is in PRA. Indeed the waiting time of each route is by definition less than  $P$  and thus the maximal process time is always less than  $T_{max}$ . Moreover a  $(P, \tau)$ -affectation of  $\mathcal{R}_{\mathcal{C}}$  can be extended into a  $(P, \tau)$ -affectation of  $\mathcal{R}'_{\mathcal{C}'}$  in the following way. For each route  $r_{u,v}$ , the time at which the message arrives is  $t(v, r_{u,v})$ , then we choose as offset for  $r_{v,u}$ ,  $-t(v, r_{u,v}) \bmod P$ . The symmetry

ensures that each new route  $r_{v,u}$  in  $\mathcal{R}'_{C'}$  uses the same times slot as  $r_{u,v}$  and thus avoid collisions.  $\square$

Let MIN-PRA be the problem, given a routage graph and an assignment, to find the minimal period  $P$  such that there is a  $P$ -periodic affectation.

**Theorem 2.** *The problem MIN-PRA cannot be approximated in polynomial time within a factor  $n^{1-o(1)}$ , with  $n$  the number of routes, unless  $\mathbf{P} = \mathbf{NP}$  even when the load is two.*

*Proof.* We reduce graph coloring to PRA. Let  $H$  be a graph instance of the  $k$ -coloring problem. We define  $\mathcal{R}$  in the following way: for each vertex  $v$  in  $H$ , there is a route  $r_v$  in  $\mathcal{R}$ . Two routes  $r_v$  and  $r_u$  share an arc if and only if  $(u, v)$  is an edge in  $H$ ; this arc is the only one shared by these two routes. All arcs are of delay 0.

Observe that the existence of a  $k$ -coloring of  $H$  is equivalent to the existence of a  $(k, 1)$ -periodic affectation in  $G$ , by converting an offset of a route into a color of a vertex and reciprocally. Therefore if we can approximate the minimum value of  $P$  within some factor, we could approximate the minimal number of colors needed to color a graph within the same factor. The proof follows from the hardness of approximability of finding a minimal coloring [2].  $\square$

In particular, this reduction shows that even with small maximal load, the minimal period can be large.

### 3.2 Tractable cases of PRA

In this section, we present a few polynomial cases, in particular when the conflict depth is one.

The problem PALL seems to be hard to solve, even for very simple classes of graphs, as seen in the next section.

## 4 The Star Topology

In this section, we consider graphs with a very simple topology that we call the **star topology**. First, for each arc  $(u, v)$ , there is also an arc  $(v, u)$  with the same weight. Moreover, there is a special arc, the central arc, which is shared by all routes. All routes consist from an arc from its source to the central source node, denoted by  $c_s$ , then the central arc to  $c_t$ , the central target node, and

an arc to its target. In addition to those central nodes, there are two sets of vertices,  $S$  and  $T$ , of cardinality  $n$  and  $\mathcal{C}$  a symmetric assignment from  $S$  to  $T$ . The routes are the directed paths of the form  $s_i, c_s, c_t, t_i$  and  $t_i, c_t, c_s, s_i$ .

We assume the weight of the central arc to be 0 since it appears in every route, its value does not matter when considering affectations. Collisions between messages can only appear at node  $c_s$  on the way forward and at node  $c_t$  on the way back.

Let us call **forward period** and **backward period** the time windows in respectively  $c_s$  and  $c_t$ . A message issued by the source  $s_1$  at time  $m_{s_1}$  will reach  $c_s$  at time  $m_{s_1} + t(c_s, r_{s_1})$  in the forward period, and  $c_t$  at time  $m_{c(s_1)} + t(c_t, r_{c(s_1)})$  in the backward period. A  $(P, \tau)$ -periodic affectation consist in choosing  $\forall i \in n, m_i$ , and  $m_{c(s_i)}$  such that, for any couples of routes  $(r_{s_j}, r_{s_k}), j, k \in n$ , we have  $[t(c_s, r_j)] \cap [t(c_s, r_k)] = \emptyset$ . and for any couples of routes  $(r_{c(s_j)}, r_{c(s_k)}), j, k \in n$ , we have  $[t(c_s, r_{c(s_j)})] \cap [t(c_s, r_{c(s_k)})] = \emptyset$

## 4.1 Solving PALL without waiting times

In this subsection, we deal with a simpler version of the problem PALL. We ask for a  $(P, \tau)$ -periodic affectation with all waiting times equal to 0. In that case  $T_{max}$  is not relevant anymore. Since  $w_i = 0$ , choosing  $m_i$ , the offset of the route from  $s_i$  to  $t_i$ , also sets the offset of the route from  $t_i$  to  $s_i$  to  $m_i + \lambda(r_i)$ . Moreover, in this context the weight of the arcs from  $s_i$  to  $c_s$  have no impact, therefore we assume they are equal to 0. Thus, in this case, we can consider only the forward and backward periods. The goal is now to put messages in the forward periods such that there is no collisions in the both periods.

In this section, the offsets  $m_{s_i}, i < n$  are in reality  $[t(c_s, r_{s_i})]$ , but to find the real values, there is just to change the values of the offset considering the delay of the arcs  $(s_i, c_s), \forall i$ .

### 4.1.1 Shortest-longest policy

**Algo** We present a simple policy, which works when the period is large with regards to the delay of the routes. We send the messages in order from the shortest route to the longest route, one after each others in the forward period.

The message using the shortest route is sent before the others, so it comes back to the central node before the following ones. Recursively, the second

message is sent before the others, and also will be back before the following messages. Because the second message is sent  $T$  slots after the first message ( $m_{s_2} = m_{s_1} + \tau$ , it comes back after the end of the message one:  $m_{s_1} + \tau + 2.\lambda(r_{\mathcal{C}(s_1)}) \leq m_{s_2} + 2.\lambda(r_{\mathcal{C}(s_2)})$  with  $\lambda(r_{\mathcal{C}(s_2)}) \geq \lambda(r_{\mathcal{C}(s_1)})$ .

**Period** The period given by this policy is  $P = \tau * n + 2(\lambda(r_{s_{n-1}}) - \lambda(r_{s_0}))$ , if routes  $\{r_0, \dots, r_{s_{n-1}}\}$  are ordered from the shortest to the longest.  $2.\lambda(r_{s_0})$  is the first slot in which the first message is coming back in the backward period, and  $2\lambda(r_{s_{n-1}}) + n.\tau$  is the time at which the last message has totally passed the switch. Therefore, the period only depends of the difference between the longest and the shortest route: the larger this value is, the larger the period is.

#### 4.1.2 Greedy Algorithm

We introduce a greedy algorithm to build a  $(P, \tau)$ -periodic affectation, which provably works when the period is large enough with regards to the number of routes and size of messages. In other words, we can always find a solution when the network is far from saturated.

**Proposition 2.** *There is an algorithm, which finds a  $(P, \tau)$ -periodic affectation in time  $O(n^2)$  when  $P \geq 3n\tau$ .*

*Proof.* We consider the forward period and cut it into consecutive macro slots of time of size  $\tau$ . The algorithm works in the following way: select the first route for which the offset has not been chosen. Try every offset which put the message in a free macro slot in the forward period. It also fixes the position of a message in the backward period, and we choose the first offset which does not create a collision in the backward period. Assume we choose the offset of the route  $r_{k+1}$ , we have at least  $3n - k$  free macro-slots, since  $P \geq 3n\tau$ . Each of these  $3n - k$  possible offset values translates into  $3n - k$  positions of messages in the backward period. All these positions are separated by at least  $\tau$  slots. There are already  $k$  messages of size  $\tau$  in the backward period. One such message can intersect at most  $2k$  potential positions, therefore amongst the possible  $3n - k$  positions, there are  $3n - k - 2k$  which are without collision. Since  $k < n$ , one of the choice is without collision, which proves that the algorithm terminates and find a  $(P, \tau)$ -periodic affectation. To ensure a complexity linear in  $n$ , it is enough to maintain a list of the free slices in the forward period and a list of the free intervals in the backward period.  $\square$

TODO: Avec une structure de données plus maligne on doit pouvoir faire n, non ?

---

**Algorithm 1** Greedy affectation

---

**Input:**  $\mathcal{R}_C$ , period  $P$

**Output:** A  $P$ -periodic affectation in  $p \leq P$ , or FAILURE

$P1[P]$  slots of size  $\tau$  in forward period.

$P2[P]$  slots of size  $\tau$  in backward period.

**for all** source  $i$  in  $S$  **do**

**for all** slot  $j$  in  $P1$  **do**

**if**  $P1[j]$  is free AND  $P2[j + \lambda(r_i)]$  is free **then**

$m_{s_i} \leftarrow j$

**end if**

**if** No intervals are found for  $i$  **then**

        return FAILURE

**end if**

**end for**

**end for**

---

#### 4.1.3 Exhaustive generation

---

**Algorithm 2** Exhaustive Generation

---

**Input:** A routage graph  $\mathcal{R}_C$ , period  $P$ , packet size  $\tau$

**Output:**  $(P, \tau)$ -periodic affectation of  $\mathcal{R}_C$

Forward-budget  $\leftarrow P - n * \tau$

Backward-budget  $\leftarrow P - n * \tau$

Free-Intervals  $\leftarrow$  list of free intervals, init to  $[0; P[$

**for all** route  $i$  in  $\mathcal{R}_C$  **do**

**for all**  $j$  in Free-Intervals **do**

**if** Message of the route  $i$  does not collides with scheduled routes **then**

$m_{s_i} \leftarrow$  the first slot of Free-Intervals[ $j$ ]

            Split the Free-Intervals considering the new packet

            Forward-budget  $\leftarrow$  Forward-budget - *lost size*

            Backward-budget  $\leftarrow$  Backward-budget - *lost size*

            call Exhaustive Generation on remaining routes

**end if**

**end for**

**end for**

---

**Lost size**, is the size lost when an interval is too few to put another packet.  
 Ex : if the interval  $[250; 3250[$  receives a packet of size 2500, there is 500 slots lost, because there is no way to uses the slots for another packet.

This algorithm enumerates all the solutions by traversing a tree. The leaves of the tree are the  $(P\tau)$ -periodic affectations, and the nodes are partial solutions. A partial solution is a choice of a starting time for a subset of the routes. For each route, the algorithm tries every possible starting offset until it finds one

available (that allows the message to come back without collisions). When a route have been scheduled, it take another route that have not been scheduled yet. This creates a new sub-tree in which the algorithm will try every possible starting offset too, and create a sub-tree on the following route too. If no offset are available for a route, this means that the partial solution is not good, so the algorithm backtracks over the tree that is, it goes back to the father of the current sub-tree. Once a leaf is obtained, the algorithm stops and return the scheduling.

To reduce the number of useless calculation, in each time we add another packet, we consider the lost size in both periods, thus, we know when a period has no many great enough free area to put a packet.

### **4.2.3 Results**

#### **Random**

#### **Distributions**

## **5 Conclusion**

Open questions. Can we improve the results if:

- The routes are smaller than the size of a message.
- The routes are smaller than the period.
- The largest difference between two routes is smallest than one of these parameters

On a general graph:

- The routing is coherent
- The graph is symmetric
